

PRODUCT RECOMMENDATION · LISFDC

Read LinkedIn and Salesforce from the operator's own browser.

LISFDC is a Chrome extension that sits in a signed-in browser session. It scrapes the LinkedIn page the operator already has open, scrapes the Salesforce page they already have open, and shows both extracts in one side panel. Salesforce is view-and-import only. No writes. No clicks. No CRM actions.

Prepared for

Review. Confidential to the recipient. Iterate letterhead; LISFDC is the subject, not the mark.

Status

Recommendation. Intent diagrams in this edition. Signed interface frames replace them when the initial design is complete. Nothing is published to a store.

Repository (private). github.com/jasoaco79/LISFDC · why, design, install, and handoff live in the repo.

Date 2 September 2026

Intent Bypass datacenter blocks by working inside a real logged-in Chrome profile. Import what is on screen. Do not operate Salesforce.

This brief does not authorize a live install beyond the operator's own machine. Design frames are not a license to write to Salesforce.

The choice the operator cannot make today

LinkedIn treats a request from a datacenter as automation. A signed-in Chrome profile on the operator's own machine is a normal session. LISFDC is built for that session: it does not log in for them, it does not carry cookies to another computer, and it does not fetch LinkedIn from a server farm.

Salesforce is already open in the same Chrome. The operator needs the visible record next to the LinkedIn page — name, object, identifier, header fields — without the extension pressing buttons, editing fields, or posting to the CRM.

What LISFDC is

- A Chrome Manifest V3 extension, loaded unpacked from the private repo.
- A side panel that holds the last LinkedIn scrape and the last Salesforce scrape.
- User-initiated scrape of the current tab only.

What LISFDC is not

- Not a Salesforce robot. No clicks, no writes, no navigation of the CRM.
- Not a cookie exporter, proxy, or headless browser.
- Not a mass crawler, InMail tool, or auto-connect.
- Not a Chrome Web Store listing.

Locked for this edition

- Salesforce: scrape the open page. Import visible information. No actions.
- LinkedIn: scrape the open logged-in tab. Optional: the operator types a LinkedIn URL and opens it in that same tab.
- Storage: last extracts on the local machine only.
- Hosts limited to LinkedIn and Salesforce. No all-sites permission.

Figures on the following pages teach the path. They are not screenshots of LinkedIn or Salesforce, and they are not a likeness of any person.

How the operator uses it

One Chrome profile. Two tabs they already use. The extension never signs in on their behalf.

- 1 **Stay in their own Chrome**
The operator is already signed in to LinkedIn and Salesforce in the same profile they use every day. LISFDC is installed into that profile. A lab or datacenter browser is the wrong place.
- 2 **Load the extension unpacked**
Clone or download github.com/jasoaco79/LISFDC (private). In Chrome: Extensions, Developer mode, Load unpacked, point at the extension folder. Pin LISFDC. Open the side panel. There is no store listing and no password prompt from us.
- 3 **Open the LinkedIn page they care about**
A profile, a search list, or a company page — already in the browser. They press Scrape LinkedIn. The side panel fills with name, headline, location, and current role when those are on the page. If the layout is unexpected or they are signed out, the panel says so instead of guessing.
- 4 **Open the Salesforce record they care about**
A Lightning or classic record they already have open. They press Scrape Salesforce. The panel imports what is visible: record name, object type, identifier from the address, header fields. The extension does not click, edit, save, or create anything in Salesforce.
- 5 **Read both extracts together**
LinkedIn on one side, Salesforce on the other. Last scrape stays on the machine until they scrape again. That is the whole daily loop.

If they need a different LinkedIn URL, they may type it and open it in the existing LinkedIn tab, then scrape. They do not drive Salesforce that way.

The path, as a picture

LinkedIn

Scrape the current tab. Optional typed URL opens in that tab. No connect, no message, no like, no follow from the extension.

Salesforce

Scrape the current record page. Import visible fields. No API write, no button press, no record update, no CRM navigation by the extension.

Where the work lives

Private repository github.com/jasoaco79/LISFDC. The repo is the long form: why, design, install, end-user process, and handoff. This PDF is the sendable stamp. Product code arrives on a branch and a review; it is not merged until you say.

Out of scope, and what we need back

Not in this edition

- Writing back to Salesforce
- Matching or enrichment between the two extracts
- A public store listing
- Any transfer of session cookies or identity to another machine
- Unattended harvest of search results

What we need back

- Yes / no / mark-up on the five-step operator path.
- Yes that Salesforce remains scrape-only.
- When initial design frames exist, swap them for Figure 1 and send this brief.
- No live distribution until you confirm.

Install, in one pass

1. Open the private repo github.com/jasoaco79/LISFDC.
2. Take a local copy of the extension folder.
3. Chrome → Extensions → Developer mode → Load unpacked.
4. Open LinkedIn (signed in) and Salesforce (signed in) in that same profile.
5. Scrape LinkedIn. Scrape Salesforce. Read the panel. Stop.

If the panel reports signed-out or unexpected layout, the operator signs in with their own credentials in the normal site — never in LISFDC.
